
Interplay between observational and randomized perspectives on drug safety and efficacy

- Robert J Glynn
- Divisions of Pharmacoepidemiology & Pharmacoeconomics & Preventive Medicine, Brigham & Women's Hospital, Boston

- Disclosure: I will present perspectives on medication safety and efficacy and have received funding from grants to BWH from AstraZeneca, Bristol-Myers Squibb, Kowa and Novartis, as well as the NIH

Outline: observations within trials, and a trialist perspective in observations

1. A surprising side effect in a trial: diabetes in JUPITER

2. Observations motivating trials: was CIRT built on poor epidemiology?

3. What to make of an unexpected benefit: cancer in CANTOS

4. Trials as the paradigm for observations: is a placebo referent coherent?

5. Building observations into trials: mediation in CANTOS

The JUPITER trial

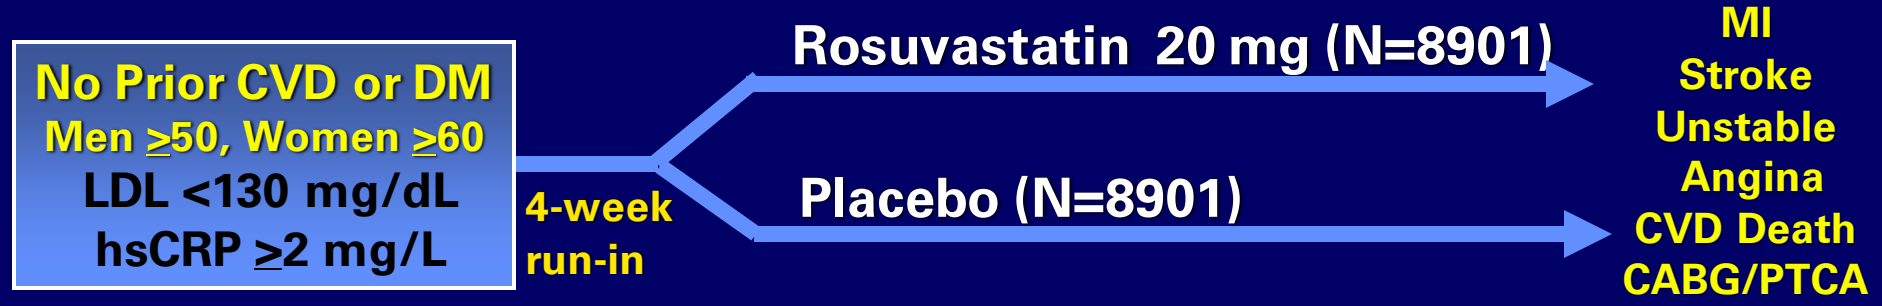
The primary objective was to investigate whether long-term treatment with rosuvastatin 20 mg decreases the rate of first major cardiovascular events compared with placebo in patients with low to normal LDL-C but at increased cardiovascular risk as identified by elevated CRP levels

Ridker PM. *Circulation* 2003; **108**: 2292–2297

JUPITER
Trial Design

JUPITER

Multi-National Randomized Double Blind Placebo Controlled Trial of Rosuvastatin in the Prevention of Cardiovascular Events Among Individuals With Low LDL and Elevated hsCRP



Argentina, Belgium, Brazil, Bulgaria, Canada, Chile, Colombia, Costa Rica, Denmark, El Salvador, Estonia, Germany, Israel, Mexico, Netherlands, Norway, Panama, Poland, Romania, Russia, South Africa, Switzerland, United Kingdom, Uruguay, United States, Venezuela

Circulation 2003;108:2292-2297.

Statins and diabetes: the JUPITER surprise

- Elevated levels of high sensitivity C-reactive protein (hsCRP) and interleukin-6 (IL-6) independently predict incident diabetes mellitus*
- Statin treatment reduces levels of inflammatory markers†
- The JUPITER trial pre-specified evaluation of the risk of diabetes as a secondary endpoint
- Almost no prior evidence was available from statin trials on this outcome

*Pradhan AD, Manson JE, Rifai N, Buring JE, Ridker PM. C-reactive protein, interleukin 6, and risk of developing type 2 diabetes mellitus. JAMA 2001; 286(3):327-34.

† Albert MA, Danielson E, Rifai N, Ridker PM; PRINCE Investigators. Effect of statin therapy on C-reactive protein levels: the pravastatin inflammation/CRP evaluation (PRINCE): a randomized trial and cohort study. JAMA 2001; 286(1):64-70.

JUPITER timeline

First randomization: March 14, 2003

Last randomization: December 15, 2006

Pre-specified stopping boundary crossed: September 7, 2007

Termination for efficacy: March 30, 2008

Last patient visit: August 20, 2008

Incident DM and HgbA1c change in JUPITER

September 7, 2007 DSMB meeting			
Treatment	Rosuvastatin	Placebo	P-value
HgbA1c 2-yr change, median (IQR)	0.2% (0.1-0.4)	0.1% (0.0-0.3)	<0.001
Incident diabetes cases, rate/1,000 pyrs	39, 2.8	22, 1.6	0.037
March 30, 2008 DSMB meeting			
HgbA1c 2-yr change, median (IQR)	0.3% (0.1-0.4)	0.2% (0.0-0.3)	<0.001
HgbA1c 3-yr change, median (IQR)	0.3% (0.1-0.4)	0.2% (0.0-0.3)	<0.001
Incident diabetes (cases/pyrs) rate	71, 3.7	40, 2.1	0.004

Diabetes in JUPITER: implications

- After final database closure, the diabetes risk associated with rosuvastatin was somewhat attenuated, but still present: HR 1.25; 95% CI: 1.09-1.45*
- A subsequent meta-analysis, including previous statin trials without reported diabetes effects, confirmed the signal from JUPITER, and showed apparently higher risk with more intensive statin regimens†
- Follow-up analyses in JUPITER showed the diabetes risk was mostly confined to those with multiple diabetes risk factors at baseline, and these individuals had strong cardiovascular benefits††

*Ridker PM, Danielson E, Fonseca FA, et al. Rosuvastatin to prevent vascular events in men and women with elevated C-reactive protein. N Engl J Med 2008; 359(21):2195-207.

†Preiss D, Seshasai SR, Welsh P, et al. Risk of incident diabetes with intensive-dose compared with moderate-dose statin therapy: a meta-analysis. JAMA 2011;305(24):2556-64.

††Ridker PM, Pradhan A, MacFadyen JG, et al. Cardiovascular benefits and diabetes risks of statin therapy in primary prevention: an analysis from the JUPITER trial. Lancet 2012; 380(9841):565-71.

Diabetes in JUPITER: follow-up of potential causes

- Follow-up biomarker analyses found no strong predictors of diabetes in statin initiators
- Rosuvastatin treatment was associated with an average weight gain of 0.85 pounds over the mean 2-year treatment period relative to placebo (95% CI: 0.47-1.24)
- Perhaps some subjects are particularly susceptible to weight gain on statins: 13.4% of randomized subjects gained 10+ pounds during follow-up, and the odds of this gain were higher in statin treated subjects: OR 1.25; 95% CI: 1.14-1.38

Trials are built on observations: the example of CIRT

- Both basic science and clinical evidence are needed to justify a trial
- Often the epidemiologic evidence is key
- Numerous pharmacoepidemiological studies supported a trial of methotrexate to reduce inflammation and thereby CVD risk
- Was the Cardiovascular Inflammation Reduction Trial built on sand?

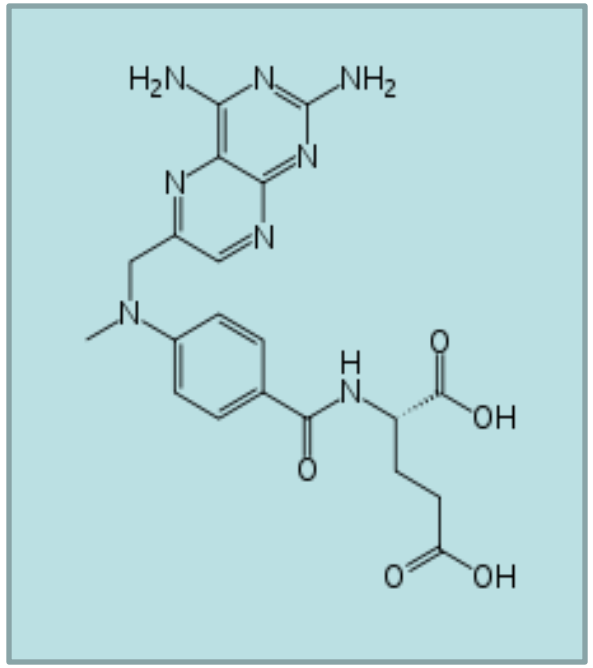
Can Inflammation Reduction, in the Absence of Lipid Lowering, Reduce Cardiovascular Event Rates?

Courtesy of Ed Yeh, MD

Cardiovascular Inflammation Reduction Trial (CIRT)

Low-Dose Methotrexate: 15 to 20 mg po weekly + folic acid



- **Used weekly as first line therapy for rheumatoid arthritis and psoriatic arthritis.**
- **Enviable safety record with over 40 years of use among older individuals with similar co-morbidities as those who have suffered a prior heart attack.**
- **Inexpensive and widely used, unlikely to have any unknown off-target effects.**
- **Guidelines for safe use already exist from the American College of Rheumatology.**
- **Mechanism of anti-inflammatory effect uncertain, likely due to adenosine mediated effects.**

Cardiovascular Inflammation Reduction Trial (CIRT)

Observational non-randomized evidence suggests a reduction in vascular events among patients with RA and Psoriasis treated with low-dose methotrexate

Cohort	Group	HR* (95 % CI)	Endpoint	Exposure

63 withdrew consent
2,244 known vital status, alive*
83 dead
5 unknown vital status

Rationale for stopping CIRT

- Absence of benefit on the primary endpoint, meeting a prespecified criterion for futility
- No heterogeneity of effect by category of baseline hsCRP level, or treatment effect on hsCRP
- Adherence below that assumed in the baseline power calculation
- Safety concern related to skin cancer

Time trends in biomarker levels by treatment

What to make of an unexpected benefit: cancer in CANTOS

The Canakinumab Anti-Inflammatory Thrombosis Outcomes Study (CANTOS) tested whether drug treatment to lower inflammation without affecting lipid levels would reduce rates of cardiovascular events in patients with stable CVD

The trial's DSMB had almost no external evidence on the safety and side effects of the drug

Integration of risks and benefits during interim monitoring is challenging

CANTOS monitoring plan

- **CANTOS designed to compare each active dose (50, 150, or 300 mg quarterly) to placebo**
- **Alpha allocated (40%, 40%, 20%) to the separate tests of the (50, 150, 300 mg) doses**
- **Secondary endpoints only tested if the primary hypothesis was rejected for that dose**
- **Futility analyses scheduled upon accrual of 25, 50 and 75% of targeted 1,400 primary endpoints**
- **Efficacy analyses upon accrual of 50 and 75% of targeted endpoints**
- **Alpha of .002 and .008 spent at interim analyses, so that .0490 remained for final analysis**

CANTOS timeline

- **First randomization: April 28, 2011**
- **Last (of 10,061) randomization: March 3, 2014**
- **Interim futility analysis: June 30, 2014**
- **Interim efficacy/futility analyses: June 26, 2015 and July 21, 2016**
- **Last patient visit: June 2017**
- **Trial results:**

Cancer concerns in monitoring CANTOS

- The CANTOS protocol was mute on cancer protection or risks
- The DSMB had no experience with canakinumab
- Some concern was expressed that an anti-inflammatory drug might also be immunosuppressive
- International regulatory agencies requested careful trial monitoring for cancer risk

PM Ridker et al. Lancet 2017

RCT as paradigm for causal efficacy, safety, and comparative effectiveness research

- Observational CER studies should parallel randomized trials, with background information used to focus on similar, but alternatively treated patients before outcome evaluation*
- Valid causal inference requires clear articulation of the treatment assignment mechanism and that subjects have non-zero probability of each treatment (positivity assumption)
- Double-blind design equalizes expectations of participants and their evaluators, visit frequency, and assessment at visits
- When placebo controls are warranted, these subjects are fully evaluated and willing to initiate therapy at baseline

Outline

Discrepant findings for preventive therapies in observational vs randomized studies

Parallel selection and survival bias concerns arise in studies of preventive drugs and healthy workers

Potential selection occurs throughout follow-up: healthy starters and sick stoppers

Optimal time scales in pharmacoepidemiology

New user designs and the value of active referent groups

Distinguish placebo controls and non-user referents

- Placebo controls are often natural, appropriate referents for evaluation of safety and efficacy in randomized trials
- Non-user referents in observational studies differ in important ways:
- Not clearly eligible or willing to initiate therapy
- No clear date of initiation
- No comparable assessment of treatment duration
- Questionable comparability in covariate and perhaps outcome assessment

Three paradoxes with non-user referents

Among hospitalized, older people enrolled in state-sponsored drug benefits programs, diabetes diagnosis and treatment were associated with enhanced survival vs no dx or rx

Across 20 commonly used classes of drugs, users vs non-users of several classes had markedly reduced death rates, of a magnitude inconsistent with randomized evidence

Focused analysis (e.g. propensity score matching) did little to reduce the magnitude of the incredible reduction in the hazard of death in users vs non-users of lipid-lowering drugs

Selective recording and treatment of DM

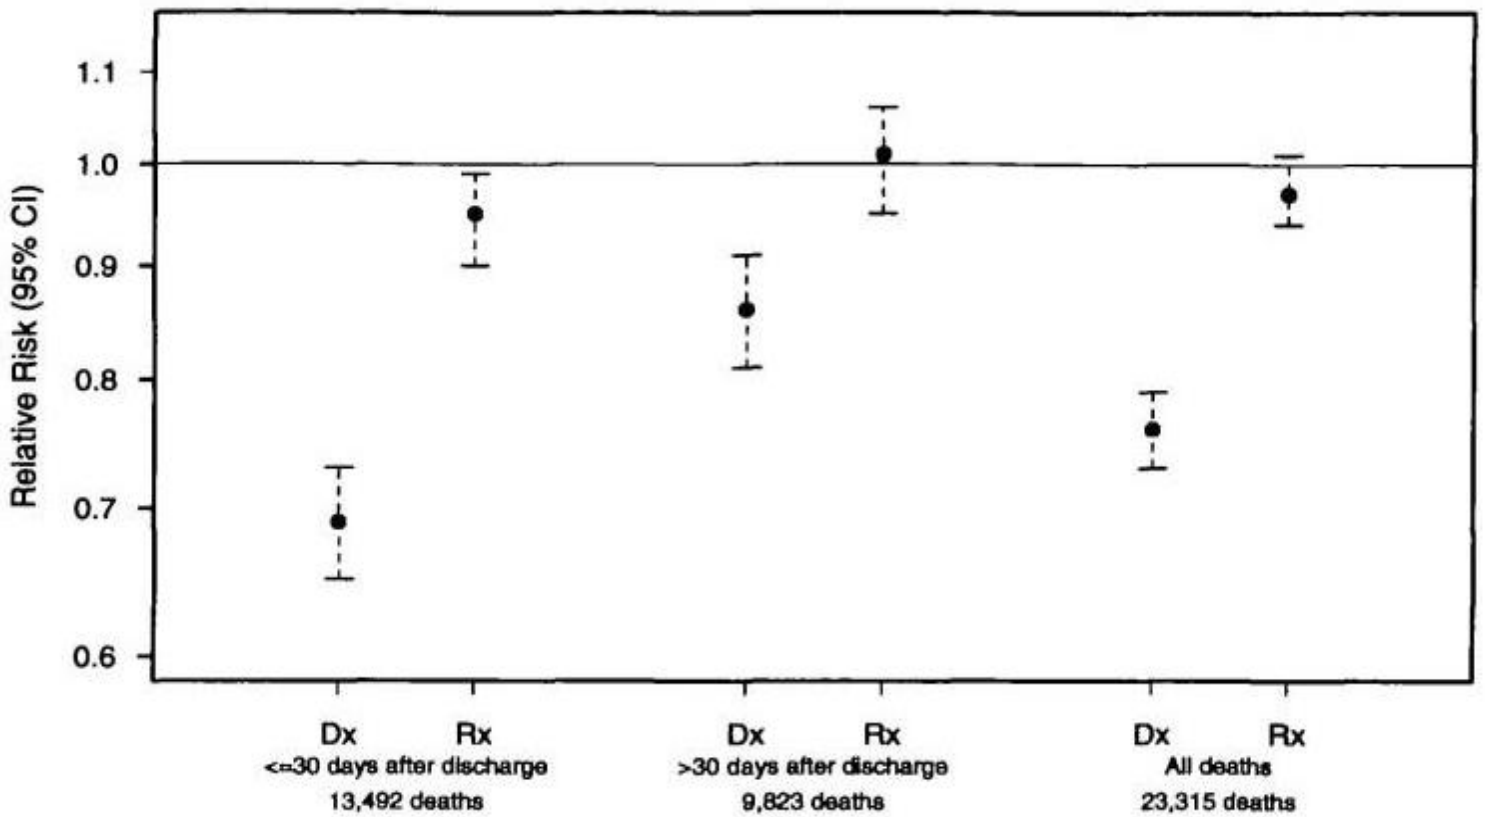

FIGURE 1. Relative risk of death associated with a diagnosis or treatment of diabetes among 81,700 elderly residents of New Jersey, 1989–1991, adjusted for age, sex, race, nursing home residence, reimbursement program, number of different drugs, and the modified Charlson index. Dx, incidence rate ratio and 95% confidence interval comparing those with a diagnosis of diabetes with those without this diagnosis; Rx, incidence rate ratio and 95% confidence interval comparing those using hypoglycemic drugs with those not using these drugs.

Value of new user designs*

Effects of a drug may vary by duration of use, e.g. for hormone therapy or coxibs

RCTs control precisely for time on therapy

Confounders affecting initiation may differ from those affecting persistence

With prevalent users, need to consider propensity to start and propensity to persist: these may differ

Stoppers of preventive drugs are often sick (healthy starter/sick stopper bias)

Risk factors may be affected by use of study drugs

May not be possible to control for these factors on the causal pathway if measured long after initiation

*WA Ray. Am J Epidemiol 2003; 158: 915-920

Emulation of RCTs with placebo controls

- Results of the ongoing RCT-DUPLICATE program*
- “Overall, agreement between RCT and RWE estimates was good for all antidiabetic trials except those that compared a DPP-4 inhibitor with placebo.”
- Emulations of these trials used second-generation sulfonylureas as a proxy for placebo. Active comparators can decrease confounding if they are used interchangeably, but are not a perfect emulation of a placebo add-on group.
- If patients with unmeasured frailty and lower socioeconomic status more often used the older and less expensive sulfonylureas, then bias toward a protective effect for DPP-4 inhibitors would be expected, as was found in the emulations

*Franklin JM, Patorno E, Desai RJ, et al. Emulating Randomized Clinical Trials With Nonrandomized Real-World Evidence Studies: First Results From the RCT DUPLICATE Initiative. Circulation 2021; 143(10):1002-1013.

Observations in trials to elucidate mechanisms: mediation of the cancer effects in CANTOS by inflammatory markers

1. Can we illuminate the pathway whereby canakinumab appears to reduce rates of cancer death and incident lung cancer in the CANTOS trial?

2. A previous mediation analysis examined the role of inflammation reduction on reduced rates of anemia in this trial

*Vallurupalli M, MacFadyen JG, Glynn RJ, et al. Effects of Interleukin-1β Inhibition on Incident Anemia: Exploratory Analyses From a Randomized Trial. Ann Intern Med. 2020; 172(8):523-532.

Rationale for mediation analysis in RCTs

- Mediation analysis in an RCT aims to elucidate the mechanism whereby the assigned treatment achieves its effect
- Specifically aims to partition the treatment effect into its indirect (mediated) effect through the mediator and its residual direct effect
- Can identify treatment responders at an early time point
- And point to the best targets for refined future interventions

Challenges to causal mediation analysis in RCTs

- Variables measured after randomization may be affected by measured and unmeasured baseline factors
- Treatment nonadherence can affect both mediator and outcome
- Early drop-outs and those with missed visits have missing mediator levels
- Likely sensitivity of estimates to mediator measurement and assumed forms of the treatment-mediator and mediator-outcome models
- Many trialists are skeptical of control for post-randomization variables
- Subgroups defined after randomization by a variable influenced by treatment are called “improper” and such subgroup analyses can mislead*
- Related to skepticism of surrogate markers†

*S Yusuf et al. JAMA 1991; †RL Prentice Stat Med 1989; TR Fleming and DL DeMets Ann Intern Med 1996

Assumptions required for causal mediation analysis

1. No unmeasured treatment-outcome confounders
2. No unmeasured treatment-mediator confounders
3. No unmeasured mediator-outcome confounders
4. No mediator-outcome confounder that is also affected by treatment*

*TJ Vanderweele Annu Rev Public Health 2016

Design of mediation analyses in CANTOS

- Population: the 10,061 randomized subjects in CANTOS
- Outcomes (2 correlated cancer events): time to incident lung cancer (n=129) and fatal cancer (n=196)
- Exposure: active canakinumab (pooling 3 dose groups) vs placebo
- Mediators (Six considered): 1) hsCRP < 2 mg/L; or 2) ≤ 1.8 mg/L at 3 months; or 3) 100*(log(hsCRP at 3 months) – log(hsCRP at baseline)); or 4) log(hsCRP) at 3 months; or 5) IL6 <1.65 ng/L at 3 months; or 6) 100*(log(IL6 at 3 months)-log(IL6 at baseline))
- Confounders (assumed the same for both prediction of mediator and control of mediator-outcome association): age, gender, baseline log(hsCRP) or log(IL6), current and former smoking, BMI, waist circumference, height, exercise, alcohol consumption, DM, COPD, HF, Afib, PAD, statin, aspirin, other anticoagulants, EGFR, HgbA1c, and Albumin.
- Also consider exposure by mediator interaction in prediction of time to outcomes

Mediation definitions

- Controlled direct effect: $Y_{a,m} - Y_{a^*,m}$
- This effect is the contrast between the counterfactual outcome if the individual were exposed at A = a and the counterfactual outcome if the same individual were exposed at A = a*, with the mediator set to a fixed level M=m.
- Natural direct effect: $Y_{a,M(a^*)} - Y_{a^*,M(a^*)}$
- This effect is the contrast between the counterfactual outcome if the individual were exposed at A = a and the counterfactual outcome if the same individual were exposed at A = a*, with the mediator assuming whatever value it would have taken at the reference value of the exposure A = a*.

Richiardi L, Rellocco R, Zugna D. Int J Epidemiol 2013; 42: 1511-1519.

Mediation definitions (cont.)

- Natural indirect effect: $Y_{a,M(a)} - Y_{a,M(a^*)}$
- This effect is the contrast, having set the exposure at level A = a, between the counterfactual outcome if the mediator assumed whatever value it would have taken at a value of the exposure A = a and the counterfactual outcome if the mediator assumed whatever value it would have taken at a reference value of the exposure A = a*.

Richiardi L, Rellocco R, Zugna D. Int J Epidemiol 2013; 42: 1511-1519.

Estimation of confounder adjusted mediation effects

- Use the SAS macro of Valeri and VanderWeele
- Fit a model for the expected value of the mediator, given exposure and confounders

$$E(M|A,C) = \beta_0 + \beta_1 a + \beta'_2 c$$

- We use linear regression for continuous mediators, and logistic regression for a dichotomous mediator
- Fit a proportional hazards model for time to the cancer outcome, given exposure, mediator, and confounders

$$\lambda_T(t|a,m,c) = \lambda_T(t|0,0,0)\exp(\gamma_1 a + \gamma_2 m + \gamma_3 am + \gamma'_4 c)$$

- Make a rare disease assumption; with more common outcomes we would use an accelerated failure time model

L Valeri & T VanderWeele; Epidemiology 2015

Estimation of mediation effects (continued)

- Assuming no unmeasured confounding and correctly specified models, obtain estimates on the hazard ratio scale
- Estimate the controlled direct effect by:

$$\lambda_{Tam}(t|c)/\lambda_{Ta*m}(t|c) = \exp\{(\gamma_1+\gamma_3 m)(a-a*)\}$$

- Estimate the natural direct effect by:

$$\lambda_{TaMa*}(t|c)/\lambda_{Ta*Ma*}(t|c) \approx \exp[\{\gamma_1+\gamma_3(\beta_0+\beta_1 a^*+\beta'_2 c+\gamma_2\sigma^2)\}(a-a^*) + 0.5\gamma^2_3\sigma^2(a^2-a^{*2})],$$

where σ^2 is the mediation regression model error variance

- Estimate the natural indirect effect by:

$$\lambda_{TaMa}(t|c)/\lambda_{TaMa*}(t|c) \approx \exp\{(\gamma_2\beta_1+\gamma_3\beta_1 a)(a-a^*)\}$$

Summary

- We used mediation analysis to clarify pathways whereby IL-1β treatment with canakinumab might reduce rates of lung cancer and other fatal cancers
- Each of several measures of achieved level or change in hsCRP or IL-6 strongly mediated the effect of canakinumab, as reflected by substantial and significant estimates of indirect effects of treatment through these pathways
- While active canakinumab treatment was associated with reduced rates of both outcomes, direct effects of canakinumab were considerably weaker and non-significant upon control for the mediation effects
- For both outcomes, continuous measures of mediators showed stronger mediation effects, likely reflecting more precise control relative to dichotomous measures
- While measures of hsCRP showed stronger mediation relative to IL-6 for fatal cancer, the converse was true for lung cancer, although smaller sample size for IL-6 analyses limited such comparisons
